

MESOLIPO INJECTION CONSENT FORM

I, _____ consent to the treatment known as the Mesolipo Injection treatments. This treatment has been explained to me and I have had the opportunity to ask questions regarding the procedure. I understand that the results of my improvement are variable. I also don't take blood thinners that may affect my bleeding capability and that might cause complications to this procedure. I have been informed and understand the risks and benefits of these treatments .

The following points have been discussed with me:

Potential benefits of the proposed procedure

- Possible alternative procedures
- Probability of success . The clinical evolution of mesolipo injection data suggests that most clients achieve their goal in the treated area on average; clients see some results after 4-6 mesolipo injection treatments . In order to obtain faster and better results , it is suggested to follow certain instructions given by the physician and sometimes to combine with other procedures .
- Reasonably anticipated consequences if the procedure is not performed
- Most likely possible risks involved with the proposed procedure and subsequent healing period, including but not limited to allergies , infection, scarring and/or bruising . The effects are not permanent; it takes 4-5 days to heal.

• Post treatment instructions .

I am aware of the following possible experience with mesolipo injection:

Discomfort : Minimal pain may be experienced during mesolipo injection due to actual injection and some medications cause burning sensation over the affected area .

Bruising /Swelling / Inflammation/ Infection: With mesolipo bruising or the area treated may occur . Additionally , there may be some swelling noted, especially after treatment . Finally, skin infection is a possibility although rare, whenever skin procedure is performed.

Wound Healing: Mesolipo injection can result in swelling , bruising , or blistering on the treated areas , which may require one week to heal. Allergy: During the healing process , there is a possibility that the treated area can become red and itchy .

Scarring: Scarring is a rare occurrence, but it is a possibility when the skin surface is disrupted. To minimize scarring , it is important to have an assessment before treatment .

I agree on photo taking and use for documentation purposes
